NOTE TO: George LaRocca, PM 15

SUBJECT: Corrections to the Avermectin TAS Analysis of 7/6/89

FROM: J. R. Tomerlin

J.R. Tomerlin 7/7/89

I provided a TAS analysis for proposed avermectin tolerances on citrus dated 7/6/89. This analysis contained two errors which should be corrected. First, the RfD used in the chronic analysis is 0.0004 mg/kg body weight/day, not 0.004 mg/kg/day as indicated in the memorandum.

Secondly, the acute analysis I reported used the wrong study. The NOEL for the acute exposure analysis is in fact 0.06 mg/kg body weight from a mouse teratology study, not 0.12 mg/kg body weight from the 2 generation mouse reproduction study. I misunderstood Bill Dykstra earlier and thought he said that the NOEL from the rat study was appropriate for the acute analysis, which is not what he told me.

The change in the acute NOEL changes the Margins of Safety I reported. The average MOS reported on page 3 of my 7/6/89 memo should be 1580, not 3160. The minimum MOS using tolerances is 125, not 250; and the minimum MOS using anticipated residues is 250, not 500.

I will correct the draft FR notice to be consistent with the proper NOELs that were used in the analysis.

MEMORANDUM

OFFICE OF
PESTICIDES AND TOXIC SUBSTANCES

SUBJECT: Chronic and Acute Dietary Exposure Analysis for the
Proposed Use of Avermectin on Citrus,
PP#8F3592/FAP#8H5550

FROM: J. Robert Tomerlin, Ph.D.
Tolerance Assessment System Staff
HED/SACB (H7509C)

THROUGH: Reto Engler, Ph.D.
Chief, Science Analysis and Coordination Branch
Health Effects Division (H7509C)

TO: George LaRocca, PM 15
Insecticide-Rodenticide Branch
Registration Division (H7505C)

Action Requested

Provide estimates of chronic and acute exposure to avermectin from published tolerances and the proposed use on citrus using anticipated residues where available.

Discussion

corrected

1. Toxicology Endpoint: The routine chronic TAS analysis used a reference dose (ADI) of 0.004 mg/kg body weight/day, based upon a NOEL of 0.12 mg/kg body weight/day and an uncertainty factor of 300 from a 2 generation rat reproduction study. This value has been approved by HED (3/30/89) and Agency (4/20/89) reference dose committees.

The acute exposure analysis was conducted using the NOEL of 0.12 mg/kg body weight for developmental toxicity from the 2 generation rat reproduction study (personal communication, W. Dykstra).

2. Residue Information: Food uses evaluated were published tolerances from 40 CFR 180.449 and the proposed use on citrus. Anticipated residues were developed from processing studies using field trial data for citrus, citrus juice, cottonseed, and extrapolated from animal feeding studies for milk (V. F. Boyd memo, 6/29/89). A summary of the residue information used in the analysis is attached as Table 1.

3. Chronic Exposure Analysis: The TAS chronic exposure analysis uses tolerance level residues and 100 per cent crop treated to estimate the Theoretical Maximum Residue Contribution (TMRC) for the overall U.S. population and 22 population subgroups. Using anticipated residues, it is possible to calculate the Anticipated Residue Contribution (ARC). TMRC and ARC exposure summaries for the overall U.S. population and all 22 TAS population groups are shown in Table 2. Exposure estimates calculated from anticipated residues (ARC) for the overall U.S. population and the two most highly exposed TAS population groups are summarized in the following table.

Avermectin Exposure Summary Using Anticipated Residues

	Overall U.S. Population	Non-Nurs. Infants	Children Aged 1 - 6
Published Tolerances	< 0.000001 ^a	< 0.000001	< 0.000001
Cottonseed	< 0.1 ^b	< 0.1	< 0.1
PP#8F3592	0.000115 28.8	0.000258 64.5	0.000298 74.6
TOTALS	0.000115 28.8	0.000258 64.5	0.000298 74.6

^aExposure estimate in mg/kg body weight/day.

^bExposure expressed in per cent of the ADI.

4. Acute Exposure Analysis: The TAS acute exposure analysis estimates the distribution of single-day exposures for the overall U.S. population and certain population subgroups. The analysis evaluates individual food consumption, as reported by respondents in the 1977-78 USDA Nationwide Food Consumption Survey, and accumulates exposure to avermectin for each food consumed for which a tolerance has been established. Each analysis assumes that avermectin residues were uniformly present in the entire commodity supply.

The toxicologic endpoint pertains to developmental toxicity. The TAS population group of interest in this analysis is women aged 13 and above, which is the TAS population group most closely approximating women of child-bearing age. The Margin of Safety (MOS) for the average female consumer may be calculated according to the following relationship:

$$\text{Average MOS} = \text{NOEL} / \text{Exposure (ARC)}$$

Avermectin Chronic and Acute Dietary Exposure Analyses, page 3

For avermectin, this would equate to:

$$\text{Average MOS} = \frac{0.12}{0.66} \text{ mg/kg body weight} / 0.000038 \text{ mg/kg body weight}$$
$$= 3160 \text{ } 1580$$

Even using tolerance level residues, no woman of child-bearing age is expected to ingest any more than 0.00048 mg/kg body weight of avermectin at one time, which translates to a minimum MOS of 125/250. Using anticipated residues, the minimum MOS for women of child-bearing age is 500/250

5. Comments: The proposed tolerance on citrus increases exposure from 21 to 114 per cent of the ADI using tolerances and from 19 to 74 per cent of the ADI using anticipated residues. The use of anticipated residue data resulted in exposure estimates that did not exceed the ADI for any TAS population group.

Even using tolerance level residues in the acute exposure analysis, no one in the appropriate population group is expected to have an MOS for developmental toxicity less than 250
